Senior Blockchain Engineer

Blockchain-native engineer experienced in architecting decentralised systems from protocol design through production deployment. Built a reorg-safe multi-chain blockchain listener and KMS-encrypted wallet management engine for a production grade escrow platform — using a Kafka outbox architecture to guarantee exactly-once deposit detection and zero-loss fund custody across five chains. Built a multi-agent AI system trained for executing on-chain transactions across 7+ chains via natural language. Designed systems where failure modes are explicit, trust assumptions are minimal, and correctness is enforced at the protocol level.

EXPERIENCE

WeiBlocks, Pakistan

March 2024 - Present

Senior Blockchain Engineer

- Led the blockchain architecture and all on-chain financial infrastructure for [Escrowly](#) across a cross-functional engineering team — owning the deposit detection layer, custodial wallet infrastructure, and event-driven service mesh from design to production; a multi-chain crypto escrow platform built on a 12-service NestJS mesh with a 6-topic Kafka event architecture across 5 chains (Ethereum, BSC, Polygon, Solana, Tron), bringing fiat-grade escrow guarantees to crypto-native transactions for goods, domains, vehicles, and milestone-based work. [Live](#) ↗
- Architected a reorg-safe blockchain listener with chain-aware confirmation tuning, automated backlog recovery, and multi-provider RPC failover — eliminating fraudulent reorged deposits and removing third-party dependency from the most critical settlement path.
- Drove an ~80% reduction in RPC infrastructure cost through targeted polling-loop optimization, while sustaining real-time deposit detection at production scale across all 5 chains.
- Built the custodial wallet service on an AWS KMS-backed encryption model with hot / funding / cold tiering, and integrated it into an event-driven microservices mesh with atomic state-and-event delivery — achieving a zero fund-loss guarantee under partial failure.
- Developed **TrAider**, an AI-driven natural-language trading agent spanning Solana and EVM chains, that converts free-form chat into on-chain swaps, transfers, token launches, and portfolio analytics — collapsing the complexity of DEX UIs and on-chain mechanics into a single conversational interface for non-technical traders.
- Architected a dual-LLM dispatch model that pairs each chain with the provider best suited to its trade complexity, with a two-stage LLM pipeline that classifies intent on the way in and converts raw on-chain results into natural-language replies on the way out.
- Integrated 7 major DEX and aggregator protocols across both chains to deliver best-execution trade routing — surfacing the optimal venue per token without exposing routing decisions to the user.
- Hardened the platform with end-to-end custodial security (encrypted-at-rest keys, fresh per-operation decryption) and an automated pre-trade security screen that surfaces honeypot, blacklist, and rug-risk signals on every contract before signing.

Ahmad software , Pakistan

Sep 2023 – Feb 2024

Blockchain Engineer

- Built **DocTracer** a tamper-evident enterprise document platform that combines immutable cloud storage, operational state, and a permissioned Hyperledger Fabric ledger into a single integrity model — making document history defensible for legal, compliance, and regulatory use cases without trusting any individual operator or cloud provider.

- Built a triple-source verification engine that re-validates every document against three independent sources of truth and pinpoints the exact source of tamper
- Implemented PII-aware on-chain privacy using Fabric's private-data primitives, keeping signer identities and sensitive material off the public ledger while preserving cryptographic proof-of-signature.
- Produced court-defensible PDF and ZIP evidence bundles for legal and regulatory submissions, turning blockchain-anchored proofs into deliverables that survive external scrutiny.
- Optimised and rescued a multi-signature milestone-escrow contract that had grown to the brink of the EIP-170 deployment limit — establishing a repeatable optimization playbook for future EVM work. [code ↗](#)
- Reduced deployed bytecode by 60% (24.186 KiB → 9.697 KiB) and initcode by 58%, pulling the contract clear of the EIP-170 contract-size limit with full behavioral parity and a 100% test pass rate.
- Applied a seven-technique systematic optimization framework — spanning storage layout, state-machine consolidation, error-handling redesign, and compiler tuning — turning gas optimization from intuitive micro-tips into a measurable, repeatable engineering discipline.
- Delivered a per-technique impact breakdown that lets future optimization work be prioritized by measured bytecode-delta rather than folklore — converting deep EVM knowledge into a reusable optimization playbook.

WeiBlocks, Pakistan Blockchain Engineer

March 2022 - August 2023

- Built and shipped [Hestiya](#) — a live, blockchain-native platform for issuing and trading tokenized carbon credits; certificates established under the UN Paris Agreement (Article 6) that represent one tonne of CO₂ removed or avoided, used by corporations worldwide to meet net-zero and ESG commitments under frameworks like CDP, SBTi, and the GHG Protocol — a market projected to reach \$50B+ by 2030, historically plagued by opacity, double-counting, and fragmented registries that Hestiya replaces with on-chain transparency. [Live ↗](#)
- Engineered the full on-chain credit lifecycle — project onboarding, vintage-year issuance, primary sale, peer-to-peer secondary trading, and permanent verifiable retirement — on a UUPS-upgradeable contract suite that tracks ownership per project, vintage, and holder, replacing trust in centralized registries with an immutable cryptographic audit trail.
- Validated the contract suite through 120 unit, integration, and fuzz tests spanning access control violations, marketplace state integrity, settlement edge cases, and adversarial forfeiture scenarios — including boundary fuzzing against 300-vintage payloads and concurrent multi-signer flows — achieving 100% pass rate across all happy-path and attack-surface cases.

Core Competencies

Programming Languages: Solidity, JavaScript, TypeScript

Backend Technologies: Node.js, Express.js, Nest.js, FastAPI, REST, GraphQL, Kafka, RabbitMQ, Hardhat, Foundry.

Databases: PostgreSQL, MongoDB, IPFS, Pinata, Redis, DynamoDB, MySQL, Supabase, Firebase

Blockchains: Ethereum, Polygon, BSC, Solana, Hedera, Hyperledger, Tron

Interests: Quantum Physics, Cryptography, Post Quantum Cryptography

EDUCATION

COMSATS University Islamabad, Bachelor of Science in Computer Science
